Data Sending/Fetching Services

The entire task of transporting data from or to an external resource, checking the returned result of that transport, and then executing follow-up tasks based on that result, is referred to as a 'data transport process' and is handled by DataTransportProcessorService. All other services shown here are injected dependencies. DataTransportResultCheckService checks if initial result has an error, and if so, takes charge of error handling. If no error, the result is passed to RunPostSuccessTasksService.
